

$$TR = P = AR = MR = D$$

HW#11 Due November 24, 2020

3. Consider total cost and total revenue given in the following table:

Quantity	0	1	2	3	4	5	6	7
Total cost	\$8	9	10	11	13	19	27	37
Total revenue	\$0	8	16	24	32	40	48	56

MR = MC

- Calculate profit for each quantity. How much should the firm produce to maximize profit?
- Calculate marginal revenue and marginal cost for each quantity. Graph them. (Hint: Put the points between whole numbers. For example, the marginal cost between 2 and 3 should be graphed at $2\frac{1}{2}$.) At what quantity do these curves cross? How does this relate to your answer to [part \(a\)](#)?
- Can you tell whether this firm is in a competitive industry? If so, can you tell whether the industry is in a long-run equilibrium?

7. A profit-maximizing firm in a competitive market is currently producing 100 units of output. It has average revenue of \$10, average total cost of \$8, and fixed cost of \$200.

- What is its profit?
- What is its marginal cost?
- What is its average variable cost?
- Is the efficient scale of the firm more than, less than, or exactly 100 units?

i.e. Is AC at its minimum?

3.) a) between Quantity 5 and 6

MC = MR when producing at Q (5, 8)

MC = 8
MR = 8
} Intersected

- c) Perfect Competition because $MR = P = D = AR$ or MR has the same price according to quantity and the graph of MR is horizontal line.

$$7) \quad Q = 100 \quad AR = \$10 \quad ATC = \$8 \quad FC = \$200 \quad P = AR = MR = D$$

$$\begin{aligned} a) \quad TR = PQ &= P(100) = 10(100) \\ TC &= 200 + 8(100) = 1000 \end{aligned} \quad \left. \vphantom{\begin{aligned} TR &= PQ \\ TC &= 200 + 8(100) \end{aligned}} \right\} \rightarrow (-)$$

$$\text{Profit} = 0$$

$$b) \quad MC = 8$$

$$c) \quad AVC = 8$$

$$d) \quad MC = 8$$

$$AC = 8$$

If they produce less than 100 unit, they will gain more profit.

But if they produce more than 100 unit, they will start to lose money or loss.
