

EE325 Introductory Econometrics (Section 1 semester 1/2020)

Assignment 4

Instruction: Write your answer in either paper or digital paper. However, if you write on paper, please scan it and save as a PDF file. Submission is via BE-Moodle as a PDF file for both cases. (Please keep the file below 10MB as that is the maximum per file capacity for student.)

Due date: Friday, November 6, 2020 (Before 10 P.M.)

1. From the data for 46 states in the United States for 1992, results of the regression are displayed as follows.

$$\begin{aligned} \ln C_i &= 4.30 - 1.34 \ln P_i + 0.17 \ln Y_i \\ se &= (0.91) \quad (0.32) \quad (0.20) \\ \bar{R}^2 &= 0.27 \end{aligned}$$

where C_i = cigarette consumption, packs per year

P_i = real price per pack, \$ per pack

Y_i = real disposable income per capita, \$ per week

1.1) Do the estimation results follow the law of demand?

1.2) What is the elasticity of demand for cigarettes with respect to price? Is it statistically significant? If so, is it statistically different from 1?

1.3) What is the income elasticity of demand for cigarettes? Is it statistically significant? If not, what might be the reasons for it?

2. From estimating the regression equation on net financial wealth (nettfa), age of the survey respondent (age), and annual family income (inc) for people in the United States. The wealth and income variables are both recorded in thousands of dollars. The OLS estimation results for the model are given by

$$nettfa_i = \beta_1 + \beta_2 inc_i + \beta_3 age_i + u_i$$

reg nettfa inc age

2.1) Test the coefficient, in the first model, $\beta_3 < 1$ in the first model or not?

2.2) Due to estimation result by adding the age² variable or agesq. Perform the test whether we should include the quadratic term of the age variable or not? (Test for both t-test and F-test.) Also, interpret the meaning of this coefficient.

3. You are conducting an empirical investigation into the median prices of houses in 506 communities of a large metropolitan area. The sample data consist of 506 observations on the following observable variables:

P_i : the median house price in community i , in dollars;

NOX_i : the level of nitrous oxide in the air of community i , in parts per 100 million;

$DIST_i$: the weighted distance of community i from municipal area, in miles;

$ROOM_i$: the average number of rooms per house in community i ;

$STRAT_i$: the average student-teacher ratio of schools in community i .

Researcher estimates the following model of median house price. The OLS estimation results for the model are given by

$$\ln(P_i) = 11.08 - 0.9535 \ln(NOX_i) - 0.1343 \ln(DIST_i) + 0.2545 ROOM_i - 0.05245 STRAT_i$$

$$se = (0.3181) \quad (0.1167) \quad (0.04310) \quad (0.01853) \quad (0.005897)$$

$$RSS = 35.1835 \quad TSS = 84.5822$$

3.1) Interpret each of the coefficient estimates in regression equation.

3.2) Test the individual significance of each of the slope coefficient estimates for $\ln(NOX_i)$ and $ROOM_i$.

3.3) Find the R-squared, adjusted R-squared, and test the joint significance of all the slope coefficient estimates.

3.4) If researcher would like to test the proposition that the marginal effect of $\ln(NOX_i)$ on $\ln(P_i)$ equals the marginal effect of $\ln(DIST_i)$ on $\ln(P_i)$, write the restricted model and perform the test comparing restricted and unrestricted model, given that OLS estimation of this restricted regression equation yields a Residual Sum of Squares value = 41.9532.

perform the test comparing restricted and unrestricted model, given that OLS estimation of this restricted regression equation yields a Residual Sum of Squares value = 41.9532.

4. Production function (Y) of the industrial sector in Thailand. It depends on the capital factor (K) and labor factor (L) in the years 1980-2010 with the following estimation.

Model 1:

$$\ln Y_t = 18.27 + 0.536 \ln L_t + 0.024 \ln K_t$$

$$R^2 = 0.9389, RSS = 0.0124$$

Model 2:

$$\ln \left(\frac{Y}{L} \right)_t = 2.13 + 1.12 \ln \left(\frac{K}{L} \right)_t$$

$$R^2 = 0.8087, RSS = 0.0153$$

4.1) Interpret the coefficients of the independent variables in models 1 and 2.

4.2) Test the hypothesis. Is the industrial production function characterized by constant return to scale? (Hint: you can perform any type of test that you see fit.)

4.3) Can we compare the R^2 value between the two regression models? Why?

1. From the data for 46 states in the United States for 1992, results of the regression are displayed as follows.

$$\begin{aligned} \ln C_i &= 4.30 - 1.34 \ln P_i + 0.17 \ln Y_i \\ se &= (0.91) \quad (0.32) \quad (0.20) \\ \bar{R}^2 &= 0.27 \end{aligned}$$

where C_i = cigarette consumption, packs per year
 P_i = real price per pack, \$ per pack
 Y_i = real disposable income per capita, \$ per week

1.1) Do the estimation results follow the law of demand?

1.2) What is the elasticity of demand for cigarettes with respect to price? Is it statistically significant? If so, is it statistically different from 1?

1.3) What is the income elasticity of demand for cigarettes? Is it statistically significant? If not, what might be the reasons for it?

1.1) ① $H_0: \beta_2 \geq 0$

$H_a: \beta_2 < 0$

$\alpha = 0.05$

② $t_{cal} = \frac{\hat{\beta}_2 - \beta_2}{se(\hat{\beta}_2)} = \frac{-1.34 - 0}{0.32} = -4.1563$

③ $df = 46 - 3 = 43$

④ conclusion : There is enough evidence to say that
 this result follow the law of demand, $\alpha = 5\%$.

1.2) elasticity of demand for cigarettes with respect to price
 is $\alpha = -1.34$

1.3) income elasticity is $\beta = 0.17$

2. From estimating the regression equation on net financial wealth (nettfa), age of the survey respondent (age), and annual family income (inc) for people in the United States. The wealth and income variables are both recorded in thousands of dollars. The OLS estimation results for the model are given by

$$nettfa_i = \beta_1 + \beta_2 inc_i + \beta_3 age_i + u_i$$

```

2.1) Test the coefficient, in the first model, $\beta_3 < 1$ in the first model or not?

2.2) Due to estimation result by adding the age² variable or agesq. Perform the test whether we should include the quadratic term of the age variable or not? (Test for both t-test and F-test.) Also, interpret the meaning of this coefficient.

2.1) $H_0: \beta_3 \geq 1$

$H_a: \beta_3 < 1$

$\alpha = 0.05$

$$t_{cal} = \frac{\hat{\beta}_3 - \beta_3}{se(\hat{\beta}_3)} = \frac{1.0307 - 1}{0.0591} = 0.520562$$

$d.f. = n - k = 9275 - 3 = 9272$

critical value

$-t_{0.05, 9272} = -1.645$

reject H_0 if $t_{cal} < -1.645$ find that $0.520562 > -1.645$

$\therefore$ not reject H_0

$\therefore$ There is not enough evidence to say that this result $\beta_3 < 1$ in the first model.

2.2)

F-test

$$\text{nettf}_i = \beta_1 + \beta_2 \text{inc}_i + \beta_3 \text{age}_i + \beta_4 \text{age}_i^2 + u_i \quad (\text{unrestricted})$$

$$\beta_4 = 0 \quad (\text{ห้ามใส่ age}^2)$$

$$\beta_4 \neq 0 \quad (\text{ควรใส่ age}^2)$$

$$\text{nettf}_i = \beta_1 + \beta_2 \text{inc}_i + \beta_3 \text{age}_i + u_i \quad (\text{restricted})$$

$$H_0 : \beta_4 = 0$$

$$H_1 : \beta_4 \neq 0$$

$$\alpha = 0.05, \quad m = k - r = 4 - 3 = 1$$

$$\begin{aligned} F_{\text{cal}} &= \frac{RSS_R - RSS_{UR} / m}{RSS_{UR} / n - k} = \frac{R^2_{UR} - R^2_R / m}{(1 - R^2_{UR}) n - k} \\ &= \frac{(31528770.7 - 31376372.3) / 1}{31376372 / 9275 - 4} = 45.03024 \end{aligned}$$

critical value

$$F_{0.05}(1, 9271) = 3.84$$

reject H_0 if $F_{\text{cal}} > 3.84$

find that $45.03 > 3.84$

$\therefore$ reject H_0

conclusion : There is enough evidence to say that the

addition of age^2 to the model has significant, at $\alpha = 5\%$.

3.1) Interpret each of the coefficient estimates in regression equation.

$$\hat{\ln}(P_i) = \hat{\beta}_1 - \hat{\beta}_2 \ln(\text{NOX}_i) - \hat{\beta}_3 \ln(\text{DIST}_i) + \hat{\beta}_4 \text{ROOM}_i - \hat{\beta}_5 \text{STRAT}_i$$

$\hat{\beta}_1 = 11.08$; if $\ln(\text{NOX}_i) = 0$, $\ln(\text{DIST}_i) = 0$, $\text{ROOM}_i = 0$ and $\text{STRAT}_i = 0$, on average, the median house price would be equal to $\$e^{11.08} = \$64,860.88341$

$\hat{\beta}_2 = -0.9535$; As the level of nitrus oxide increase by 1%, on average, the median house price decreases by about 0.9535%, holding other variables constant.

$\hat{\beta}_3 = -0.1343$; As the weighted distance from municipal area increases by 1%, on average, the median house price decreases by about 0.1343%, holding other variables constant.

$\hat{\beta}_4 = 0.2545$; As the average number of rooms per house increases by 1 room per house, on average, the median house price increase by about $0.2545 \times 100 = 25.45\%$, holding other variables constant.

$\hat{\beta}_5 = -0.0524$; As the average student-teacher ratio of schools increases by 1 student per teacher, on average, the median house price decreases by about $0.05245 \times 100 = 5.245\%$, holding other variables constant.

3.2) Test the individual significance of each of the slope coefficient estimates for $\ln(\text{NOX}_i)$ and ROOM_i .

↳ insignificant $\beta = 0$, significant $\beta \neq 0$

$$H_0 : \beta_4 = 0$$

$$d.f = n - k = 506 - 5 = 501 = \infty$$

$$H_a : \beta_4 \neq 0$$

$$\alpha = 0.05$$

$$\begin{aligned} t_{cal} &= \frac{\hat{\beta}_4 - \beta_4}{se(\hat{\beta})} \\ &= \frac{0.2545 - 0}{0.01853} \\ &= 13.73448 \end{aligned}$$

∴ reject the null hypothesis if $t_{cal} < -1.96$

or $t_{cal} > 1.96$ find that $13.73448 > 1.96$

∴ reject H_0

conclusion

There is enough evidence to say that $\ln(\text{NOX})$ has significant on $\ln P_i$ at $\alpha = 0.05$

$$H_0 : \beta_5 = 0$$

$$d.f = n - k = 506 - 5 = 501 = \infty$$

$$H_a : \beta_5 \neq 0$$

$$\alpha = 0.05$$

$$\begin{aligned} t_{cal} &= \frac{\hat{\beta}_5 - \beta_5}{se(\hat{\beta}_5)} \\ &= \frac{-0.05245 - 0}{0.005897} \\ &= -8.89448 \end{aligned}$$

∴ reject the null hypothesis if $t_{cal} < -1.96$

or $t_{cal} > 1.96$ find that

$-8.89448 < -1.96$ ∴ reject H_0

conclusion

There is enough evidence to say that ROOM_i has significant on $\ln P_i$ at $\alpha = 0.05$

3.3) Find the R-squared, adjusted R-squared, and test the joint significance of all the slope coefficient estimates.

$$R^2 = 1 - \frac{RSS}{TSS} = 1 - \frac{35.1835}{84.5822} = 1 - 0.416 = 0.584$$

$$\begin{aligned} \text{adjust R-squared} &= 1 - (1 - R^2) \frac{n-1}{n-k} = 1 - (1 - 0.584) \frac{(505)}{(501)} \\ &= 1 - (0.416)(1.0079) \\ &= 1 - 0.4193 = 0.5807 \end{aligned}$$

test the joint ; $H_0 : \beta_2 = \beta_3 = \beta_4 = \beta_5 = 0$

$\alpha = 0.05$

H_a : Not all slope coeff. are simultaneously zero

$$F_{cal} = \frac{ESS/K-1}{RSS/n-k} = \frac{R^2/K-1}{(1-R^2)n-k} = \frac{49.3957/4}{35.1835/501} = 175.8441$$

critical value

$\therefore$ reject H_0 if $F_{cal} > 2.77$

Find that $175.8441 > 2.77 \therefore$ reject H_0

conclusion : There isn't enough evidence to say that at least one parameter isn't equal to zero, at $\alpha = 5\%$.

$F_{0.05; (4, 501)} = 2.77$

3.4) If researcher would like to test the proposition that the marginal effect of $\ln(NOX_i)$ on $\ln(P_i)$ equals the marginal effect of $\ln(DIST_i)$ on $\ln(P_i)$, write the restricted model and perform the test comparing restricted and unrestricted model, given that OLS estimation of this restricted regression equation yields a Residual Sum of Squares value = 41.9532.

$$H_0 : \beta_2 = \beta_3 \text{ or } \beta_2 - \beta_3 = 0$$

$$H_a : \beta_2 \neq \beta_3 \text{ or } \beta_2 - \beta_3 \neq 0$$

$$\alpha = 0.05$$

$$K=5, R=4$$

$$\begin{aligned} \ln(P_i) &= \beta_1 + \beta_2 \ln(NOX_i) + \beta_3 \ln(DIST_i) + \beta_4 (ROOM_i) + \beta_5 (STRAT_i) + u_i \\ &= \beta_1 + \beta_2 \ln(NOX_i) + \beta_2 \ln(DIST_i) + \beta_4 (ROOM_i) + \beta_5 (STRAT_i) + u_i \\ &= \beta_1 + \beta_2 [\ln(NOX_i) + \ln(DIST_i)] + \beta_4 (ROOM_i) + \beta_5 (STRAT_i) + u_i \\ &= \beta_1 + \beta_2 \ln(NOX_i + DIST_i) + \beta_4 (ROOM_i) + \beta_5 (STRAT_i) + u_i \quad \text{restricted} \end{aligned}$$

$$\begin{aligned} F_{cal} &= \frac{RSS_R - RSS_{UR} / m}{RSS_{UR} / n-k} = \frac{R^2_{UR} - R^2_R / m}{(1-R^2_{UR}) / n-k} = \frac{RSS_{UR} - RSS_R / m}{RSS_{UR} / n-k} \\ &= \frac{41.9532 - 35.1835 / 1}{35.1835 / 506-5} = 96.39801 \end{aligned}$$

$\therefore$ reject H_0 if $f_{cal} > 3.84$ find that $96.39801 > 3.84$

$\therefore$ reject H_0

conclusion : This isn't enough evidence to say that the marginal effect of $\ln NOX$ on $\ln P$ equal the marginal effect of $\ln DIST$ on $\ln P$; at $\alpha = 5\%$.

4. Production function (Y) of the industrial sector in Thailand. It depends on the capital factor (K) and labor factor (L) in the years 1980-2010 with the following estimation.

Model 1:

$$\ln Y_t = 18.27 + 0.536 \ln L_t + 0.024 \ln K_t$$

$$R^2 = 0.9389, RSS = 0.0124$$

Model 2:

$$\ln \left(\frac{Y}{L} \right)_t = 2.13 + 1.12 \ln \left(\frac{K}{L} \right)_t$$

$$R^2 = 0.8087, RSS = 0.0153$$

4.1) Interpret the coefficients of the independent variables in models 1 and 2.

4.2) Test the hypothesis. Is the industrial production function characterized by constant return to scale? (Hint: you can perform any type of test that you see fit.)

4.3) Can we compare the R^2 value between the two regression models? Why?

4.1) model 1 $\hat{\ln Y}_t = 18.27 + 0.53 \ln L_t + 0.1024 \ln K_t$

$\hat{\beta}_1 = 18.27$; if $\ln L_t = 0$ and $\ln K_t = 0$ on average, output would be equal to $e^{18.27}$ units

$\hat{\beta}_2 = 0.536$; As labor increase by 1%, on average, output increase by about 0.536%, holding other variables constant.

$\hat{\beta}_3 = 0.1024$; As capital increase by 1%, on average, output increase by about 0.1024%, holding other variable constant.

model 2 ; $\ln \left(\frac{Y}{L} \right)_t^{(1\%)} = \hat{\alpha}_1 + \hat{\alpha}_2 \ln \left(\frac{K}{L} \right)_t^{(1\%)}$

$\hat{\alpha}_1 = 2.13$; If $\ln(K/L) = 0$, on average, output per labor ratio (labor productivity) would be equal to $e^{2.13}$ unit

$\hat{\alpha}_2 = 1.12$; as capital per labor ratio increase by 1%, on average labor productivity increase by about 1.12%, holding other variable constant

4.2) $H_0 : \beta_2 + \beta_3 = 1$

$H_a : \beta_2 + \beta_3 \neq 1$

$\alpha = 0.05$, $m = k - r = 3.2$

$$F_{cal} = \frac{RSS_R - RSS_{UR} / m}{RSS_{UR} / (n - k)}$$

$$= \frac{0.0153 - 0.0124 / 1}{0.0124 / 31.2}$$

$= 6.54838$

critical value

$F_{0.05}(2, 28) = 4.20$

reject the null hypothesis if $f_{cal} > 4.20$

find that $6.54838 > 4.20$

$\therefore$ reject H_0

$\therefore$ there isn't enough evidence to say that this industrial production func. characterized by CRTS, at $\alpha = 5\%$.

4.3) revise

$$\text{var}(ax \pm by)$$

$$= a^2 \text{var}(x) + b^2 \text{var}(y) \pm 2ab \text{cov}(x, y)$$

$$* \text{se}(0) = \sqrt{\text{var}(0)}$$

$$\text{se}(\hat{\beta}_2 + \hat{\beta}_3) = \sqrt{\text{var}(\hat{\beta}_2 + \hat{\beta}_3)}$$

$$= \sqrt{\text{var}(\hat{\beta}_2) + \text{var}(\hat{\beta}_3) + 2\text{cov}(\hat{\beta}_2, \hat{\beta}_3)}$$

t-test

$$H_0: \beta_2 + \beta_3 = 1$$

$$H_a: \beta_2 + \beta_3 \neq 1$$

$$\alpha = 0.05$$

$$t_{cal} = \frac{(\hat{\beta}_2 + \hat{\beta}_3) - (\beta_2^1 + \beta_3^1)}{\text{se}(\hat{\beta}_2 + \hat{\beta}_3)}$$

$$= \frac{(\hat{\beta}_2 + \hat{\beta}_3) - 1}{\sqrt{\text{var}(\hat{\beta}_2) + \text{var}(\hat{\beta}_3) + 2\text{cov}(\hat{\beta}_2, \hat{\beta}_3)}}$$

$$= \frac{(0.536 + 0.024) - 1}{\sqrt{\text{var}(\hat{\beta}_2) + \text{var}(\hat{\beta}_3) + 2\text{cov}(\hat{\beta}_2, \hat{\beta}_3)}}$$

$$= \frac{(0.536 + 0.024) - 1}{\sqrt{\text{var}(\hat{\beta}_2) + \text{var}(\hat{\beta}_3) + 2\text{cov}(\hat{\beta}_2, \hat{\beta}_3)}}$$

$$= \frac{(0.536 + 0.024) - 1}{\sqrt{\text{var}(\hat{\beta}_2) + \text{var}(\hat{\beta}_3) + 2\text{cov}(\hat{\beta}_2, \hat{\beta}_3)}}$$

$$= \frac{(0.536 + 0.024) - 1}{\sqrt{\text{var}(\hat{\beta}_2) + \text{var}(\hat{\beta}_3) + 2\text{cov}(\hat{\beta}_2, \hat{\beta}_3)}}$$
