

HW#7 Due Feb 15, 2022

Mankiw Page 107

3. Suppose the price elasticity of demand for heating oil is 0.2 in the short run and 0.7 in the long run.

- a. If the price of heating oil rises from \$1.80 to \$2.20 per gallon, what happens to the quantity of heating oil demanded in the short run? In the long run? (Use the midpoint method in your calculations.)
- b. Why might this elasticity depend on the time horizon?

7. Suppose that your demand schedule for pizza is as follows:

Price	Quantity Demanded (income = \$20,000)	Quantity Demanded (income = \$24,000)
\$8	40 pizzas	50 pizzas
10	32	45
12	24	30
14	16	20
16	8	12

- a. Use the midpoint method to calculate your price elasticity of demand as the price of pizza increases from \$8 to \$10 if (i) your income is \$20,000 and (ii) your income is \$24,000.
- b. Calculate your income elasticity of demand as your income increases from \$20,000 to \$24,000 if (i) the price is \$12 and (ii) the price is \$16.

3.

a) Find midpoint elasticity: $\eta_p = \frac{Q_1 - Q_0}{(Q_1 + Q_0)/2} \left\{ \begin{array}{l} \% \Delta QD \end{array} \right\} \frac{(P_1 - P_0)}{(P_1 + P_0)/2} \left\{ \begin{array}{l} \% \Delta P \end{array} \right\}$

• Price rises from \$1.8 to \$2.2. It means that $\% \Delta P = \frac{2.2 - 1.8}{\frac{(2.2 + 1.8)}{2}} = 20\% = 0.2$

• In short run $\eta_p = \frac{\% \Delta QD}{\% \Delta P} \rightarrow -0.2 = \frac{\% \Delta QD}{0.2} \rightarrow \% \Delta QD = -0.04 = -4\%$
 quantity demand decreases 4%

b) Long-run price elasticity is higher because consumers have more time to react and find alternative source of energy to substitute to heating oil.

7.

(a) (i) income is \$20,000

$$\frac{1}{\text{slope}} \times \frac{P_1 + P_2}{2} = |n_D|$$

$$\frac{Q_1 + Q_2}{2}$$

$$\frac{1}{-\frac{1}{4}} \times \frac{8+10}{2} = |n_D|$$

$$\frac{40+32}{2}$$

$$-4 = \frac{9}{26.4} = |n_D|$$

$$\frac{-4}{\frac{1}{4}} = -1$$

ii) income is \$24,000

$$\frac{1}{\text{slope}} \times \frac{P_1 + P_2}{2} = |n_D|$$

$$\frac{Q_1 + Q_2}{2}$$

$$\frac{1}{-\frac{2}{5}} \times \frac{8+10}{2} = |n_D|$$

$$\frac{50+45}{2}$$

$$\frac{-5}{2} \times \frac{9}{\frac{95}{2}} = |n_D|$$

$$\frac{-5}{2} \times \frac{18}{95} = 0.47$$

(a) (i) income is 20,000

$$\frac{\% \Delta D}{\% \Delta I} = \frac{30-24}{24}$$

$$\frac{24,000-20,000}{20,000}$$

$$= \frac{\frac{6}{24}}{\frac{1}{5}}$$

$$= \frac{6}{24} \times 5 = \frac{30}{24} = \frac{5}{4} = 1.25 \%$$

ii) income is \$24,000

$$\frac{\% \Delta D}{\% \Delta I} = \frac{12-8}{8}$$

$$\frac{24,000-20,000}{20,000}$$

$$= \frac{\frac{4}{8}}{\frac{1}{5}}$$

$$= \frac{4}{8} \times 5 = \frac{20}{8} = \frac{5}{2}$$

$$= 2.5\%$$
