HW#5 Due September 22, 2020

Mankiw Page 107

3. Suppose the price elasticity of demand for heating oil is 0.2 in the short run and 0.7 in the long run.

   a. If the price of heating oil rises from $1.80 to $2.20 per gallon, what happens to the quantity of heating oil demanded in the short run? In the long run? (Use the midpoint method in your calculations.)

   b. Why might this elasticity depend on the time horizon?

7. Suppose that your demand schedule for pizza is as follows:

Price	Quantity Demanded (income = $20,000)	Quantity Demanded (income = $24,000)
$8	40 pizzas	50 pizzas
10	32	45
12	24	30
14	16	20
16	8	12

   a. Use the midpoint method to calculate your price elasticity of demand as the price of pizza increases from $8 to $10 if (i) your income is $20,000 and (ii) your income is $24,000.

   b. Calculate your income elasticity of demand as your income increases from $20,000 to $24,000 if (i) the price is $12 and (ii) the price is $16.

3. Suppose the price elasticity of demand for heating oil is 0.2 in the short run and 0.7 in the long run.

   a. If the price of heating oil rises from $1.80 to $2.20 per gallon, what happens to the quantity of heating oil demanded in the short run? In the long run? (Use the midpoint method in your calculations.) ↑ QD , Price

   b. Why might this elasticity depend on the time horizon?

7. Suppose that your demand schedule for pizza is as follows:

Price	Quantity Demanded (income = $20,000)	Quantity Demanded (income = $24,000)
$8	40 pizzas	50 pizzas
10	32	45
12	24	30
14	16	20
16	8	12

   a. Use the midpoint method to calculate your price elasticity of demand as the price of pizza increases from $8 to $10 if (i) your income is $20,000 and (ii) your income is $24,000.

   b. Calculate your income elasticity of demand as your income increases from $20,000 to $24,000 if (i) the price is $12 and (ii) the price is $16.

3. Suppose the price elasticity of demand for heating oil is 0.2 in the short run and 0.7 in the long run.

   a. If the price of heating oil rises from $1.80 to $2.20 per gallon, what happens to the quantity of heating oil demanded in the short run? In the long run? (Use the midpoint method in your calculations.) ขึ้น QD , Price

   b. Why might this elasticity depend on the time horizon?

(a). $E_D = \frac{\% \Delta Q_D}{\% \Delta P} = \frac{\text{Percentage change in } Q_D}{\text{Percentage change in Price}}$

From (a). price : 1.8, 2.2

E_D : 0.2 , 0.7

$\% \Delta Q_D = x$

$0.2 = \frac{x}{\frac{2.2-1.8}{2.2+1.8} \times 100}$ (2)

$0.2 = \frac{x}{20}$

$x = -4$

∴ in short run there is decrease in percentage change of quantity demand of 4.

long run. $\% \Delta Q_D = x$

$0.7 = \frac{x}{\frac{2.2-1.8}{2} \times 100}$

$0.7 = \frac{x}{20}$

$x = -1.4$ - law of demand คือ price increase demand ลด

∴ in long run there is decrease in percentage change of quantity demand of 1.4

(b). if in the long run there will be more elasticity because people can find substitutes compared to the short run.

7. Suppose that your demand schedule for pizza is as follows:

Price	Quantity Demanded (income = $20,000)	Quantity Demanded (income = $24,000)
$8	40 pizzas	50 pizzas
10	32	45
12	24	30
14	16	20
16	8	12

a. Use the midpoint method to calculate your price elasticity of demand as the price of pizza increases from $8 to $10 if (i) your income is $20,000 and (ii) your income is $24,000.

b. Calculate your income elasticity of demand as your income increases from $20,000 to $24,000 if (i) the price is $12 and (ii) the price is $16.

(a).

$$\text{Y}_D = \frac{\%\ \Delta Q_D}{\%\ \Delta P} = \frac{\text{Percentage change in } Q_D}{\text{Percentage change in Price}}$$

price : 8, 10

income : 20,000, 24,000

$$\text{Y}_D = \frac{\frac{32-40}{\frac{32+40}{2}}}{\frac{10-8}{\frac{10+8}{2}}} = \frac{\frac{-8}{36}}{\frac{2}{9}} = -\frac{8}{36} \times \frac{9}{2} = -1$$

$$\text{Y}_D = \frac{\%\ \Delta Q_D}{\%\ \Delta I} = \frac{\text{Percentage change in } Q_D}{\text{Percentage change in Income}}$$

income : 20,000, 24,000

$$\text{Y}_D = \frac{\frac{45-50}{\frac{45+50}{2}}}{\frac{10-8}{\frac{10+8}{2}}} = \frac{\frac{-5}{95}}{\frac{2}{9}} = -5\left(\frac{2}{95}\right)\left(\frac{9}{2}\right) = \left(-\frac{2}{19}\right)\left(\frac{9}{2}\right) = -\frac{9}{19}$$

(b)

$$E_D = \frac{\% \Delta Q_D}{\% \Delta I} = \frac{\text{Percentage change in } Q_D}{\text{Percentage change in Income}}$$

price : 12, 16

income : 20,000 , 24,000

(24,30)

$$E_D = \frac{\frac{30-24}{\frac{30+24}{2}}}{\frac{24{,}000-20{,}000}{\frac{24{,}000+20{,}000}{2}}} = \frac{\frac{6}{27}}{\frac{4{,}000}{44{,}000}} = \frac{\frac{2}{9}}{\frac{2}{11}} = \frac{2}{9} \times \frac{11}{2} = \frac{11}{9}$$

$$E_D = \frac{\% \Delta Q_D}{\% \Delta I} = \frac{\text{Percentage change in } Q_D}{\text{Percentage change in Income}}$$

(8,12)

$$E_D = \frac{\frac{12-8}{\frac{12+8}{2}}}{\frac{24{,}000-20{,}000}{\frac{24{,}000+20{,}000}{2}}} = \frac{\frac{4}{10}}{\frac{4{,}000}{22{,}000}} = \frac{2}{5} \times \frac{11}{2} = \frac{11}{5}$$
