

MONOCENTRIC URBANIZATION IN THAILAND

Key Issues and Recent Development in Urban Studies

EE 460: Thai Economy

Semester 1 / 2018

Thammasat University

Main topics

- (1)** The development of cities as engines of growth: status and challenges
- (2)** Policy issues of major concerns
- (3)** Availability and accessibility of micro-level data for analysis
- (4)** How to use the available data to address issues

Topic 1: The development of cities as engines of growth: status and challenges

(1) The development of cities as engines of growth: status and challenges

(1.1) Rapid expansion of area and population

Core & Suburban Population: 1947-2010
BANGKOK REGION

Cox(2012) states the following key issues of urbanization of Bangkok and its suburban areas as follows.

- **After 2000**, the **annual population growth** of Bangkok has been **2.5 times that of 1980-2000**.
- The Bangkok region – which includes the provincial level city of Bangkok and the provinces of Samat Prakan, Samut Sakhon, Pathum Thani, Nonthaburi and Nakhon Pathom – had a **population of 15 million in 2010**.
- Interestingly the growth has arisen in suburban areas. During 2000 and 2010, the **city expanded by 30%**, while the **suburban provinces grew by 66%**.

(1) The development of cities as engines of growth: status and challenges

(1.1) Rapid expansion of area and population (continued)

Cox(2012) also indicates the following main characteristics of Bangkok and its suburban areas .

- The urban area covers approximately 900 square miles (2,330 square kilometers).
- It has a population density of the urban area of 16,200 per square mile (6,200 per square kilometer).
- It is noted that this density is **1.5 times** that of the **Paris urban areas** and more than **2.5 times** that of **the Los Angeles**.

(1) The development of cities as engines of growth: status and challenges

(1.1) Rapid expansion of area and population (continued)

In addition, Cox(2012) identifies key economic outcomes influenced by Bangkok's rapid expansion as follows.

- According to Brookings Global Metro Monitor (2012), the **GDP per capita** of Bangkok is **\$23,400 annually** (based on purchasing power), which is **higher than that of main Latin America's metropolitan economies** (Brasilia, Monterrey, Buenos Aires and Sao Paulo).
- The increasing affluence of Bangkok area has induced the real estate investment, especially **inexpensive residences in suburban areas**, and also influenced the **rising private ownership of vehicles** (e.g. automobiles and motorcycles).

Although conventional views on Bangkok's rapid expansion attracting the higher density of business and residential areas, **the industrialization has been clustering in the surrounding provinces**, which are Samat Prakan, Samut Sakhon, Pathum Thani, and Nakhon Pathom.

(1) The development of cities as engines of growth: status and challenges

(1.2) Concentration of industrialization surrounding Bangkok

- Retrospectively, the clustering pattern of industrial activities around Bangkok has been occurring since 1980s. Phisit (1988) stated that it was because **Bangkok had the largest demand for manufactured products**.
- Therefore, in the first phase of industrial development, the **largest financial return on manufacturing activities** and related services was mainly from **the concentration within Bangkok's suburban areas**.
- Consequently the higher concentration has progressively **induced the economies of scale and comparative advantages**. Also this process has **continuously influenced migration from rural areas**.

(1) The development of cities as engines of growth: status and challenges

(1.3) Urban-rural migration and remittance

- As previously stated in (1.1) and (1.2), disparities in income and living condition **have been continuously induced relocation** of labor **from rural provinces to Bangkok** and its suburban areas.
- The urban-rural migration does not only incur the expansion of Bangkok and its suburban areas, but it does **indirectly influence the rural development through remittances**.
- Many studies indicate that internal **remittances have been contributing a positive consequence on income distribution** (e.g. Boonyamanond and Punpuing (2009), Paris et al. (2009) and Guest (1998)).
- Boonyamanond and Punpuing (2009), using data from the Migration Survey conducted by the National Statistical Office in 2007, identified that most of remittances were sent to the following recipients:
 - **Parents (74.6%),**
 - **Children (15.4%)**
 - Spouses (6.6%)
 - Other relatives (2.6%).

(1) The development of cities as engines of growth: status and challenges

(1.3) Urban-rural migration and remittance (continued)

- Paris et al. (2009) used a survey of 1,874 rice farming households in the Northeast, and found that **40% of their household incomes were from remittances**.
- Guest (1988) did the similar study and estimated that **remittances** could contribute around **25% of rural households' incomes**.
- Piriyaikul (2010) indicated that internal remittances were used as **daily expenses, including food purchases, investment in farms and supporting children's schooling**. These evidences clearly show the **effect on poverty alleviation**.

Topic 2: Policy issues of major concerns

(2) Policy issues of major concerns

(2.1) What have been key factors driving Bangkok as the monocentric growth pole?

[The combination of development policies and behaviors of firms and workers]

(2.2) Will Bangkok still be the single growth pole in the future?

[Technology, ageing society and AEC integration may change the spatial pattern of growth and employment]

(2.3) Will the monocentric pattern of Bangkok be replicated to create other growth poles in Thailand?

[A pattern of industrial concentration of surrounding areas and service-oriented in the central zone]

Topic 3:

Availability and accessibility of micro-level data for analysis

(3) Availability and accessibility of micro-level data

There are 3 categories of data

- **Ground surveys:** mostly produced by NSO (formal request/purchase is required).
- **Remote sensing data:** most vegetation and nightlight data are publicly available.
- **GIS-based maps:** specifically produced by government's agencies(formal request/purchase is required).

Topic 4: How to use the available data to address policy issues

Overview of Analytical Framework

Example #1: Nightlight Index

Example #1: Nightlight Index

Spatial Economic Analysis of Thailand using Satellite Data on Lights at Night

- With the public availability of **Defense Meteorological Satellite Program Operational Line Scanner (DMSP/OLS)** nighttime light data, many analyses have been using this satellite dataset to monitor and examine spatial dynamics of economic expansions. This study explores the **application of this nightlight data to the case of Thailand**, covering annual spatio-temporal data of **1992-present**.
- Results from econometrical analyses show that the values of provincial nightlight indexes are **significantly correlated with** many survey data such as the **annual provincial GDP**, the **spatial density of labor** classified by occupation and the **spatial density of industrial production**.

Analytical Framework

Example #1: Nightlight Index

```

Example #1: Nightlight Index

- These outcomes suggest that with the limitation of most current survey data in term of their coverage and spatial resolution, the nightlight indexes can **be the alternative sources indicating the magnitude of economic activities** for many fields of studies interested in Thailand's dynamic adjustment of spatio-temporal dimensions.
- Also outcomes of these analyses provide **insights on Thailand's spatial pattern of economic transformation** which are important for future policy and planning formulations.

THE INTEGRATION OF REMOTE-SENSING DATA AND ECONOMIC ANALYSIS: THE CASE OF RICE CULTIVATION IN THE NORTHEASTERN REGION OF THAILAND

Nattapong Puttanapong¹, Preesan Rakwatin², Sutee Anantsuksomsri³, Nij Tontisirin⁴, Thanasin Tanompongphandh⁵

- This study aims at delivering two main contributions, which are (1) the process of undertaking **pre-treatment on remote-sensing data and constructing vegetation indexes**, and (2) the **validation of vegetation indexes with ground data**.
- Specifically, this study shows that vegetation indexes developed based on ASA's Moderate Resolution Imaging Spectroradiometer (MODIS) satellite have an **econometrically significant relationship** with the **provincial GDP in agricultural sector** and have the **negative correlation with crop loss statistics**.

Example #2: Vegetation Index

Future applications

- These findings suggest the possibility of using remote-sensing data for **timely monitoring the economic situation of rice farmers**, which would subsequently improve insights on the **connection between the agricultural output and urban-rural migration**.
- Suttiwichienchot and Puttanapong (2014) indicate that the seasonal migration is the important mechanism of Thai economy. Specifically **switching between farm and non-farm jobs signifies the flexibility of Thai labor market**.
- This switching mechanism can be represented by **Harris-Todaro's expected-wage equation**.

Example #2: Vegetation Index

Million persons

Figure 1. Seasonal employment in agricultural and non-agricultural sectors in Thailand during 2005 – 2012.

Source: The Labor Force Survey, Ministry of Labor, Thailand

Unit: Baht

Figure 2. The time series of the deflated switching cost during 2005 - 2012

Source: Authors' calculation based on the data obtained from the Labor Force Survey, Ministry of Labor, Thailand.

Following **Harris-Todaro's concept**, the behavior of internal migration between agricultural and non-agricultural sectors can be mathematically represented by the expected wage equilibrium as shown in Eq. 1.

$$\begin{aligned}
 & \text{prob}(\text{employment}_{\text{agri}}) \cdot \text{wage}_{\text{agri}} = \\
 & \sum_{\text{nagri}} (\text{prob}(\text{employment}_{\text{nagri}}) \cdot \text{wage}_{\text{nagri}}) - \text{switching cost} \quad (1) \\
 & \text{where } \text{prob}(\text{employment}_{\text{agri}}) = \frac{\text{employment}_{\text{agri}}}{\text{total labor supply}}, \\
 & \text{and } \text{prob}(\text{employment}_{\text{nagri}}) = \frac{\text{employment}_{\text{nagri}}}{\text{total labor supply}}
 \end{aligned}$$
