

Production and Costs in the Long run

EE311

Chayun Tantivasadakarn

Faculty of Economics, Thammasat University

Production: Two Variable Inputs

- In the long-run, capital and labor are both variable.
- We can look at the output we can achieve with different combinations of capital and labor

Production: Two Variable Inputs

Isoquant Map

Derivation of an Isoquant

- From a production function $Q = K^{0.5}L^{0.5}$
- At a fixed Q , $K = Q^2/L$
- Suppose $Q = 100$, the function for this isoquant is: $K = 10000/L$
- Any combination of K & L according to the above function will always give $Q = 100$ and the slope is declining as L increases

Production: Two Variable Inputs

- Substituting Among Inputs
 - Negative slope is the **marginal rate of technical substitution (MRTS)** = dK/dL
 - **MRTS: amount by which the quantity of one input can be reduced when one extra unit of another input is used, so that output remains constant.**

Marginal Rate of Technical Substitution

MRTS and Isoquants

- We assume there is diminishing MRTS
 - Increasing labor in one unit increments from 1 to 5 results in a decreasing MRTS from 1 to $1/2$.
 - Productivity of any one input is limited
- Diminishing MRTS occurs because of diminishing returns and implies isoquants are convex.
- There is a relationship between MRTS and marginal products of inputs

MRTS and Marginal Products

As we move down the isoquant, MP_L decreases while MP_K increases. Hence $MRTS = MP_L / MP_K$ decreases

Perfect Substitutes

- Same output can be reached with mostly one input (A or C) or with equal amount of both (B)
- MRTS is constant at all points on isoquant
- $\sigma = \text{infinity}$

Fixed-Proportions Production Function

Bicycle
frames

- Same output can only be produced with one set of inputs.
- There is no substitution available between inputs.
- The output can be made with only a specific proportion of capital and labor
- $\sigma = 0$

Returns to Scale

- **Long-run production is characterized by Returns to Scale (RTS).**
- Rate at which output increases as inputs are increased proportionately
 - Constant returns to scale
 - Increasing returns to scale
 - Decreasing returns to scale

Returns to Scale

- **Constant returns to scale:** output doubles when all inputs are doubled
 - Size does not affect productivity
 - May have a large number of producers
 - Isoquants are equidistant apart

Returns to Scale

Returns to Scale

- **Increasing returns to scale:** output more than doubles when all inputs are doubled
 - Larger output associated with lower cost (cars)
 - One firm is more efficient than many (utilities)
 - The isoquants get closer together
- Reasons
 - Specialization and division of labor
 - Technical increasing returns to scale
- It leads to a declining cost per unit

Increasing Returns to Scale

Returns to Scale

- **Decreasing returns to scale:** output less than doubles when all inputs are doubled
 - Decreasing efficiency with large size
 - Reduction of entrepreneurial abilities
 - Isoquants become farther apart
- **Reasons**
 - Coordination problems, limitation of manager

Returns to Scale

Returns to Scale: Example

$$Q_0 = AL_0^\alpha K_0^\beta$$

$$Q_1 = A(mL)_0^\alpha (mK)_0^\beta, \quad m > 1$$

$$= Am^\alpha L_0^\alpha m^\beta K_0^\beta$$

$$= m^{\alpha+\beta} AL_0^\alpha K_0^\beta = m^{\alpha+\beta} Q_0$$

$\alpha + \beta > 1$, Increasing returns to scale

$\alpha + \beta = 1$, Constant returns to scale

$\alpha + \beta < 1$, Decreasing returns to scale

Cost in the Long Run

- In the long run a firm can change all of its inputs
- Assumptions
 - Two Inputs: Labor (L) & capital (K)
 - Price of input: wage rate (w), rental rate (r)
- The Isocost Line
 - A line showing all combinations of L & K that can be purchased for the same cost
 - Total cost of production is sum of firm's labor cost, wL and its capital cost rK

$$TC = wL + rK$$

Cost in the Long Run

- Rewriting TC as an equation for a straight line:
 - $K = TC/r - (w/r)L$
 - Slope of the isocost: $\Delta K / \Delta L = -\left(\frac{w}{r}\right)$
 - - w/r is the ratio of the wage rate to rental cost of capital.
 - This shows the rate at which capital can be substituted for labor with no change in cost.

Least Cost Combination of Inputs

- We will address how to minimize cost for a given level of output by combining isocosts with isoquants
- We choose the output we wish to produce and then determine how to do that at minimum cost
 - Isoquant is the quantity we wish to produce
 - Isocost is the combination of K and L that gives a set cost

Least Cost Combination of Inputs

Cost in the Long Run

$$\text{MRTS} = -\Delta K / \Delta L = \text{MP}_L / \text{MP}_K$$

$$\text{Slope of isocost line} = \Delta K / \Delta L = -w / r$$

$$\text{MP}_L / \text{MP}_K = w / r \text{ when firm minimizes cost}$$

- The minimum cost combination can then be written as:

$$\text{MP}_L / w = \text{MP}_K / r$$

- Minimum cost for a given output will occur when each dollar of input added to the production process will add an equivalent amount of output.

Input Substitution When an Input Price Change

- If the price of labor changes, then the slope of the isocost line change, w/r
- It now takes a new quantity of labor and capital to produce the output
- If price of labor increases relative to price of capital, and capital is substituted for labor

Input Substitution When an Input Price Change

If the price of labor rises, the isocost curve becomes steeper due to the change in the slope $-(w/r)$.

The new combination of K and L is used to produce Q_1 . Combination B is used in place of combination A .

Elasticity of substitution

- $\% \Delta$ in capital-labor ratio divided by the $\% \Delta$ in the slope of the isoquant

$$\sigma = \frac{\% \Delta (K/L)}{\% \Delta \text{ MRTS}} = \frac{d(K/L)}{d(\text{MRTS})} \frac{\text{MRTS}}{K/L} = \frac{\partial \ln(K/L)}{\partial \ln(\text{MRTS})}$$

$\sigma = 0$ means fixed proportion

$\sigma = \infty$ means perfect substitutes

Example

From Cobb-Douglas production function: $Q = K^\alpha L^\beta$,

$$\text{MRTS} = \frac{\text{MP}_L}{\text{MP}_K} = \frac{\beta K^\alpha L^{\beta-1}}{\alpha K^{\alpha-1} L^\beta} = \frac{\beta K}{\alpha L}$$

$$\frac{K}{L} = \frac{\alpha}{\beta} \text{MRTS}$$

$$\ln \frac{K}{L} = \ln \frac{\alpha}{\beta} + \ln \text{MRTS}$$

$$\sigma = 1$$

Elasticity of substitution

- Point *A* is more capital-intensive, and *B* is more labor-intensive.
- Moving from *A* to *B*, K/L decreases by 80% and $MRTS$ also decreases by 80% $\rightarrow \sigma = 1$

Cost in the Long Run

- Cost minimization with Varying Output Levels
 - For each level of output, there is an isocost curve showing minimum cost for that output level
 - A firm's **expansion path** shows the minimum cost combinations of labor and capital at each level of output.

A Firm's Expansion Path

A Firm's Long-Run Total Cost Curve: CRTS case

Expansion Path & Long-run Costs

- Firms expansion path has same information as long-run total cost curve
- To move from expansion path to LR cost curve
 - Find tangency with isoquant and isocost
 - Determine min cost of producing the output level selected
 - Graph output-cost combination

Long-Run Versus Short-Run Cost Curves

- In the short run some costs are fixed
- In the long run firm can change anything including plant size
 - Can produce at a lower average cost in long run than in short run
 - Capital and labor are both flexible
- We can show this by holding capital fixed in the short run and flexible in long run

The Inflexibility of Short-Run Production

Long-Run Versus Short-Run Cost Curves

- Long-Run Average Cost (LAC)
 - Most important determinant of the shape of the LR AC and MC curves is relationship between scale of the firm's operation and inputs required to min cost
- Constant Returns to Scale
 - If input is doubled, output will double
 - AC cost is constant at all levels of output.

Long-Run Versus Short-Run Cost Curves

- Increasing Returns to Scale
 - If input is doubled, output will more than double
 - AC decreases at all levels of output.
- Decreasing Returns to Scale
 - If input is doubled, output will less than double
 - AC increases at all levels of output

Short and Long-run Average Cost Curves

Long-Run Versus Short-Run Cost Curves

- Long-run marginal cost leads long-run average cost:
 - If $LMC < LAC$, LAC will fall
 - If $LMC > LAC$, LAC will rise
 - Therefore, $LMC = LAC$ at the minimum of LAC
- In special case where LAC is constant, LAC and LMC are equal

Long Run Costs

- **Economies of Scale:** a situation when LAC declines with a larger output due to
 - increasing returns to scale
 - On a larger scale, workers can better specialize
 - Firm can use more efficient machine
 - Lumpiness in investment
 - Scale can provide flexibility – managers can organize production more effectively
 - Firm may be able to get inputs at lower cost if can get quantity discounts. Lower prices might lead to different input mix

Long Run Costs

- **Diseconomies of scale:** a situation when LAC increases with a larger output due to
 - Factory space and machinery may make it more difficult for workers to do their job efficiently
 - Managing a larger firm may become more complex and inefficient as the number of tasks increase
 - Bulk discounts can no longer be utilized. Limited availability of inputs may cause price to rise

Long Run Costs

- Economies of scale are measured in terms of cost-output elasticity, E_C
- E_C is the percentage change in the cost of production resulting from a 1-percent increase in output

$$E_C = \frac{\Delta LTC / LTC}{\Delta Q / Q} = \frac{\Delta LTC / \Delta Q}{LTC / Q} = \frac{LMC}{LAC}$$

Long Run Costs

- E_C is equal to 1, $LMC = LAC$
 - Costs increase proportionately with output
 - Neither economies nor diseconomies of scale
- $E_C < 1$ when $LMC < LAC$
 - Economies of scale
 - LAC are declining
- $E_C > 1$ when $LMC > LAC$
 - Diseconomies of scale
 - Both LMC and LAC are rising

Production with Two Outputs: Economies of Scope

- Many firms produce more than one product and those products are closely linked
- Examples:
 - Chicken farm--poultry and eggs
 - Automobile company--cars and trucks
 - University--Teaching and research
 - Nation Group
 - Choke Chai Farm

Production with Two Outputs: Economies of Scope

Advantages

- Both use capital and labor.
- The firms share management resources.
- Both use the same labor skills and type of machinery.

Economies of Scope means that the production of one good reduces the cost of producing another related good.

Production with Two Outputs: Economies of Scope

- There is no direct relationship between economies of scope and economies of scale.
 - May experience economies of scope and diseconomies of scale
 - May have economies of scale and not have economies of scope

Dynamic Changes in Costs: The Learning Curve

- Firms may lower their costs not only due to economies of scope, but also due to managers and workers become more experienced at their jobs
- As management and labor gain experience with production, the firm's marginal and average costs may fall

Dynamic Changes in Costs: The Learning Curve

- Reasons
 - Speed of work increases with experience
 - Managers learn to schedule production processes more efficiently
 - More flexibility is allowed with experience.
May include more specialized tools and plant organization
 - Suppliers become more efficient passing savings to company

Dynamic Changes in Costs: The Learning Curve

- The **learning curve** measures the impact of worker's experience on the costs of production.
- It describes the relationship between a firm's cumulative output and amount of inputs needed to produce a unit of output.

The Learning Curve

Dynamic Changes in Costs: The Learning Curve

- Observations
 - New firms may experience a learning curve, not economies of scale.
 - Should increase production of many lots regardless of individual lot size
 - Older firms have relatively small gains from learning.
 - Should produce its machines in very large lots to take advantage of lower costs associated with size

Economies of Scale Versus Learning
